Prof. Dr.-Ing. Jochen H. Schiller, FU Berlin  
Prof. Dr. Timos Sellis, TU Athen

## Abstract

Constantly growing data volumes and accelerating update speeds are fundamentally changing the role of data warehousing in modern business. Data warehousing is increasingly used not only for strategic, but for operative decision making as well. More data, coming in faster and requiring immediate conversion into decisions means that organizations are confronting the need for right-time (active) data warehousing.

In parallel, great advances, both in wireless networks and respective mobile devices functioning within their proximity, enable a wide-scale adoption of mobile information systems. Mobile devices become smaller, cheaper and more powerful, being able to run more sophisticated applications and network services. With ubiquitous data access already being success critical, integrating mobile devices in existing infrastructure is a fundamental requirement.

The research field of mobile online analytical processing (mOLAP) brings the two aforementioned research and application areas together. The term mOLAP encompasses all necessary technologies for mobile information systems that enable multidimensional data access to users carrying a mobile device.

This thesis presents FCLOS, a complete client-server architecture explicitly designed for mOLAP. FCLOS exploits derivability between multidimensional data cubes in conjunction with wireless broadcast in order to become a query efficient, self adaptive and scalable mOLAP information system.

## Acknowledgements

This work was financed by the Berlin-Brandenburg Graduate School on Distributed Information Systems and carried out at the Freie Universität Berlin. Pursuing a Ph.D. in computer engineering is not a trivial task. Fortunately, during this time I had the owner and privilege to work and cooperate with some great persons.

Above all, I would like to express my gratitude to my first advisor, Professor Hans-J. Lenz. He gave me the chance to pursue my ideas in absolute freedom. His genuine interest in science has been and will be a great inspiration for me, not only for this thesis, but for the rest of my life. I also thank my fellows in the institute of Production, Information Systems and Operations Research.

I would also like to sincerely thank my second advisor, Professor Jochen Schiller. Our discussions, especially at the beginning of this work, helped me keep my feet on the ground and stay in a sound scientific direction. I also thank him for letting me participate in his research group. My fellows of the Computer Systems and Telematics group, created an entertaining working environment.

A special thanks goes to Professor Timos Sellis. The fact that he accepted to serve as an external referee of this work, especially bearing in mind his busy schedule, deeply owners me.

Furthermore, I would like to thank all professors of the Berlin-Brandenburg Graduate School on Distributed Information Systems, first for giving me the opportunity to embark on this project, and secondly for their precious feedback during our workshops. I also thank my fellows of the graduate school for our constructive discussions.

I am particularly thankful to the master thesis students Arkadiy Omelchenko and Christian Becker for their invaluable contribution to some parts of this thesis.

I would also like to thank Sarah, Nikos, the BFB and HSEC members (you know who you are) for their individual assistance.

Last but not least, I would like to express my gratitude to my parents. I would have never accomplished anything important in my life, including this thesis, without their incessant support.
